

# I-MAP: LOGBOOK (AI USAGE)

## TSMK

## LLM request

△ [ChatGPT](#) was used for this prompt.

My nvidia jetson nano isn't booting.

I've followed this totutorial <https://developer.nvidia.com/embedded/learn/get-started-jetson-nano-devkit#intro> until the point of the setup and first boot, but after the green led blinks, nothing happens.

## LLM response

If the **green LED** turns on but nothing appears on the screen during first boot, the issue is usually one of these three things (in order of probability):

1. **Power supply problem (most common)**
2. **Bad or incorrectly flashed micro-SD card**
3. **Display/cable incompatibility**

Let's go through the fastest checks.

### 1 Check your power supply (very common issue)

The **Jetson Nano** is extremely sensitive to power.

Requirements:

- **5V / 4A barrel jack** (recommended)  
or
- **5V / 2.5–3A micro-USB with a very good cable**

If the voltage drops even slightly, the board **boots briefly then freezes or shows nothing**.

#### Quick test

Try one of these:

- Use a **5V 4A barrel jack power supply**
- Or a **phone charger ≥3A with a short cable**
- Avoid cheap USB cables

If you use the **barrel jack**, make sure the **J48 jumper** is installed.

### 2 Reflash the micro-SD card

A corrupted image is another common cause.

Do this exactly:

1. Download the image again from NVIDIA.
2. **Reformat the SD card**
3. Flash with **Balena Etcher**
4. Insert the card and boot.

Tips:

- Use a **good SD card (32GB+ UHS-I)**.
- Some cheap cards cause boot failures.

## 3 Check the display

Jetson Nano sometimes fails with adapters.

Works best with:

- **HDMI → HDMI**
- **DisplayPort → DisplayPort**

Problematic:

- HDMI → DVI adapters
- HDMI → VGA adapters

Try:

- another monitor
- another HDMI cable
- another HDMI port

## **Solution**

Eventually I was able to use the micro-sub port by disconnecting the J48 jumper.
